Standards: CO₂, CH₄,
CO, N₂O, SF₆

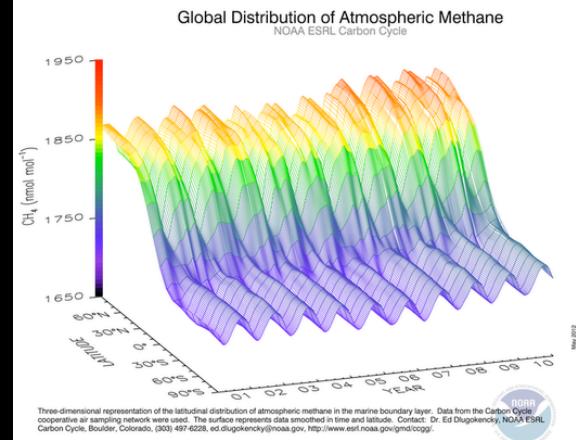

Cooperative network

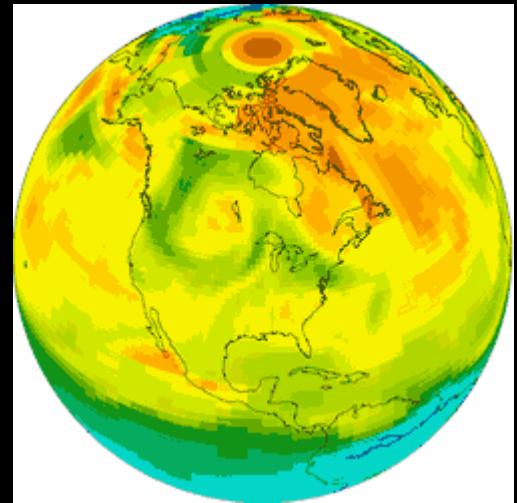

Annual Greenhouse Gas Index

The primary goal of NOAA's Carbon Cycle Group is to monitor changes in Greenhouse Gases all over the world and to try to understand what is driving those changes.

CarbonTracker – CO₂ and CH₄

Regional Studies of Greenhouse Gas

Problem:

- Most GHG emissions are aggregated at regional to local scales which means detection and verification techniques need to be developed for that scale.

Primary Goals:

- Develop and test techniques for measurement of regional greenhouse gas emission fluxes that can be scaled up to satellite observations.
- Comparison of top-down with bottom-up emission estimates.

Secondary Goals:

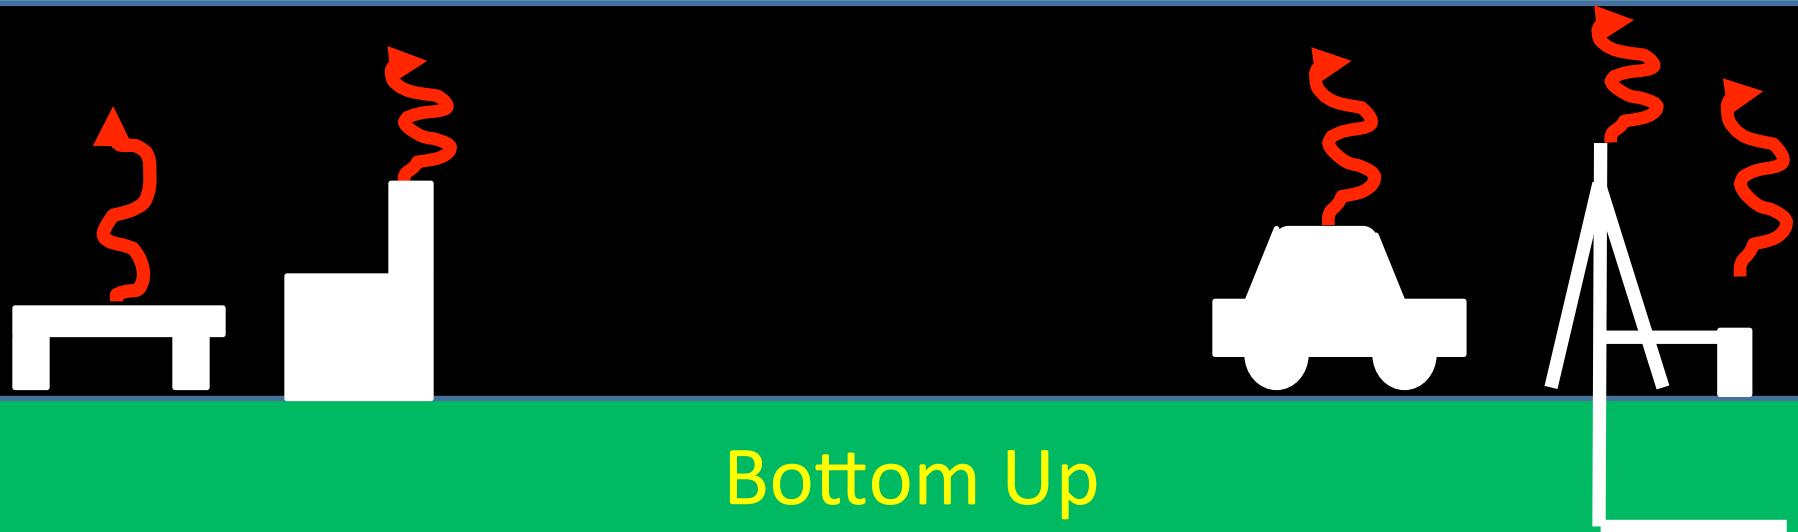

- Use emission ratios to quantify fluxes of other trace gases, e.g. CO, halocarbons, hydrocarbons
- Partition GHG flux into biological (natural) and fossil fuel components.
- Identify and characterize point sources distribution.

The simple picture

Top Down

Direct measurements of enhancements (ΔC)

Direct measurement of flux ($\langle w'c' \rangle$)

Bottom Up

“INVENTORY”

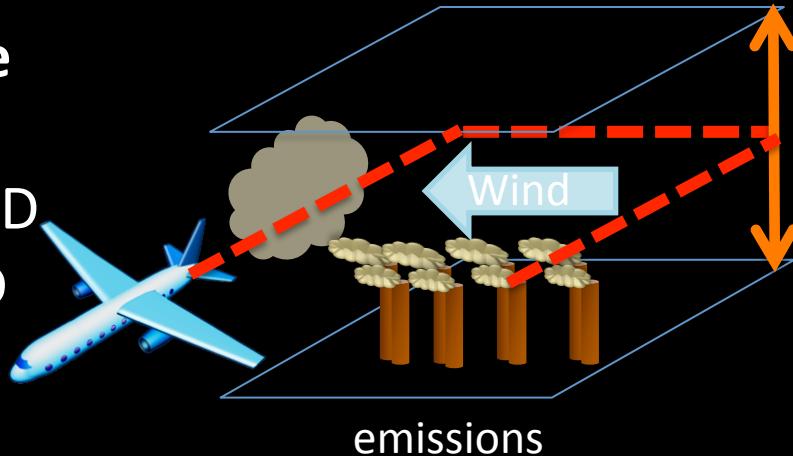

Process based estimate of emissions

Some processes can be well tracked based on economic data while other processes are not well tracked

Multi-scale/level approach

Mass Balance

- Umich
- NOAA/GMD
- NOAA/CSD

Total basin emissions
and large-scale source
allocation

Point Source identification

- Scientific aviation
- NASA/JPL

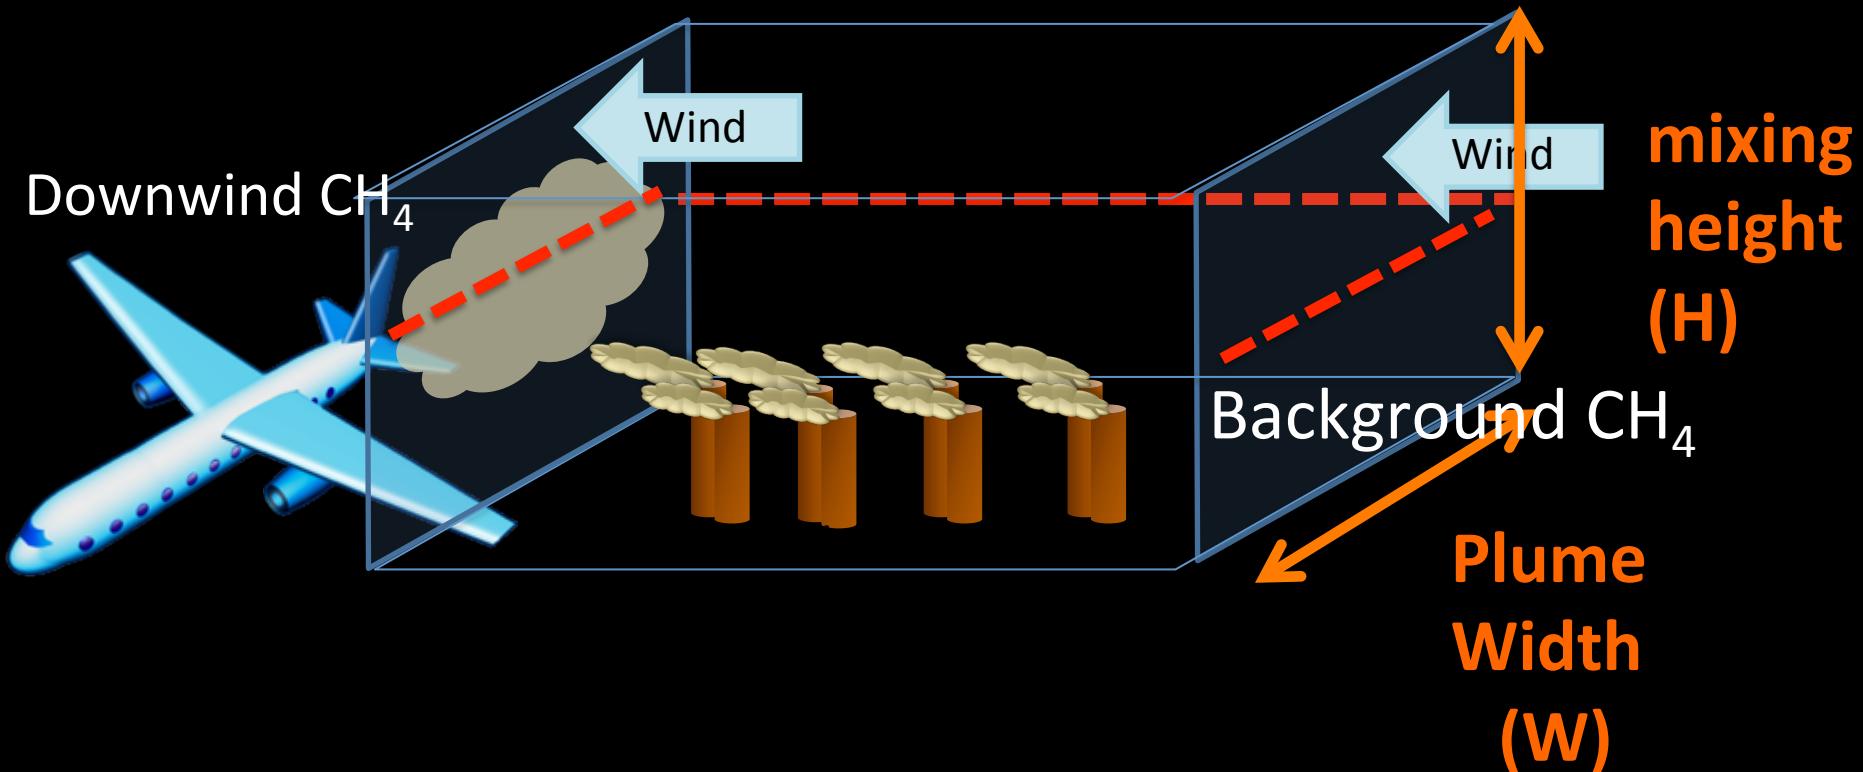

Large emitter site
location and emissions
quantification

- U of Colorado
- NOAA/GMD
- LANL

Process level emissions
verification and
emissions profile (e.g.
 $\text{CH}_4/\text{C}_2\text{H}_6$)

Aircraft Mass Balance Method

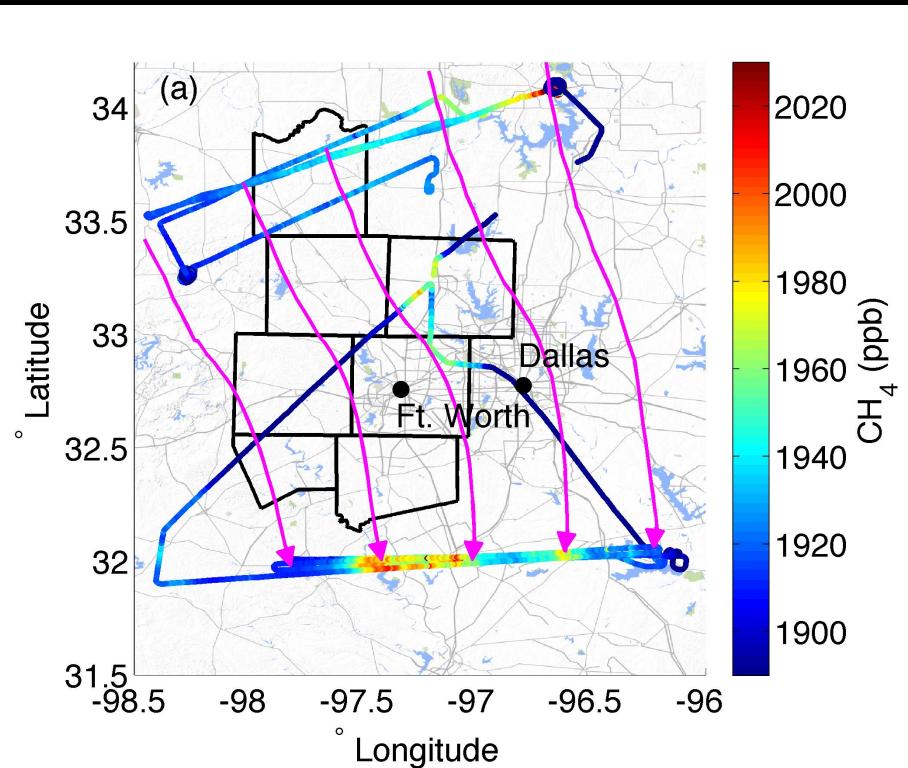

$$\text{CH}_4 \text{ emissions} = [\Delta\text{CH}_4] \times [\text{wind speed}] \times H \times W$$

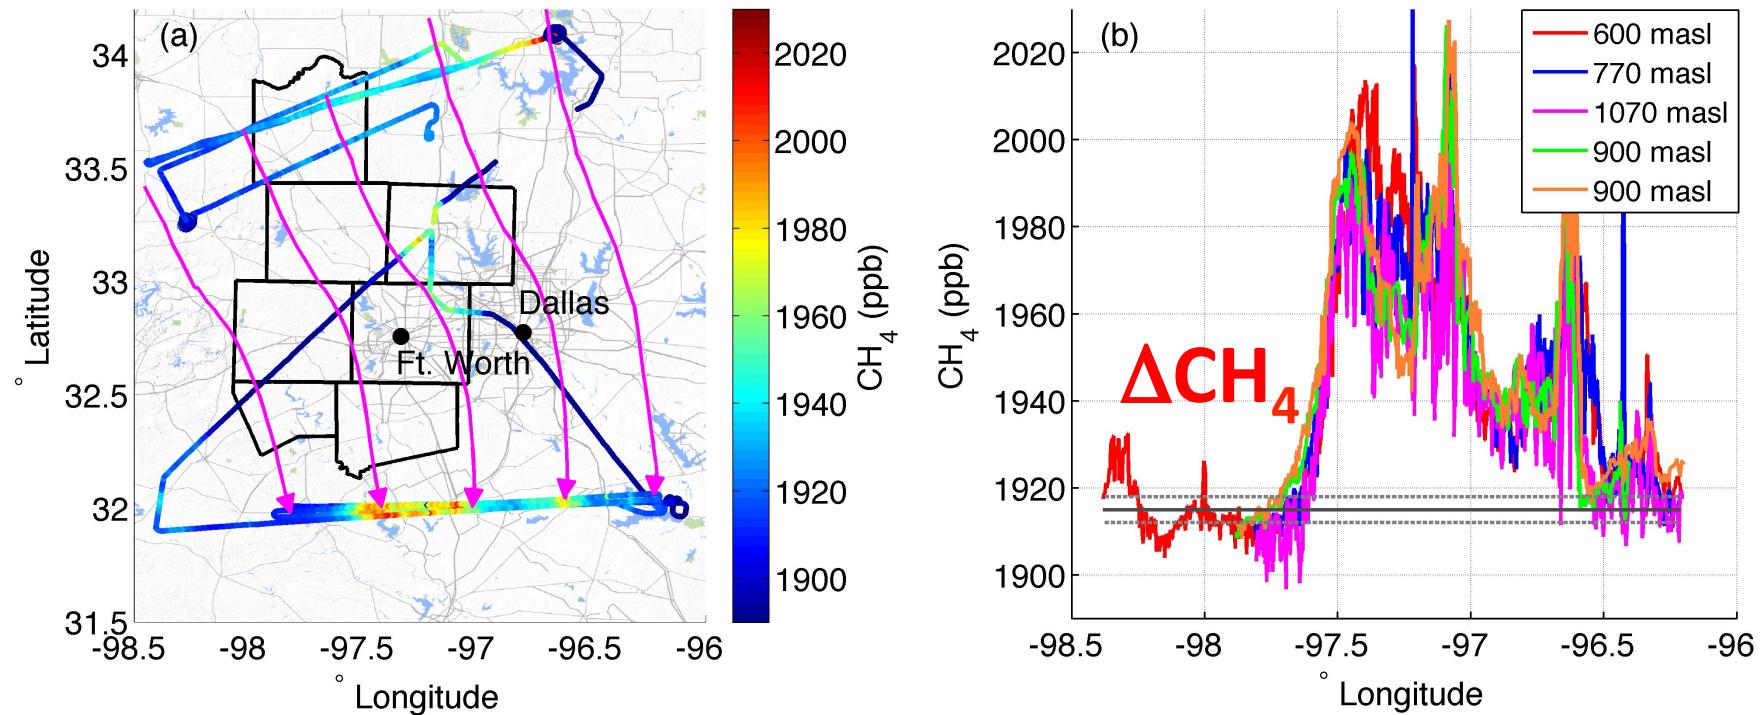

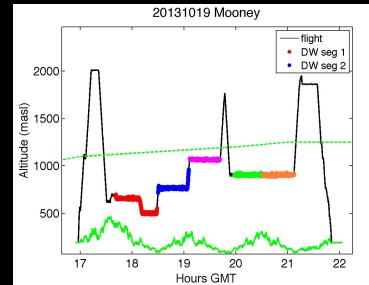

Background CH_4 - Downwind CH_4

Mass Balance example

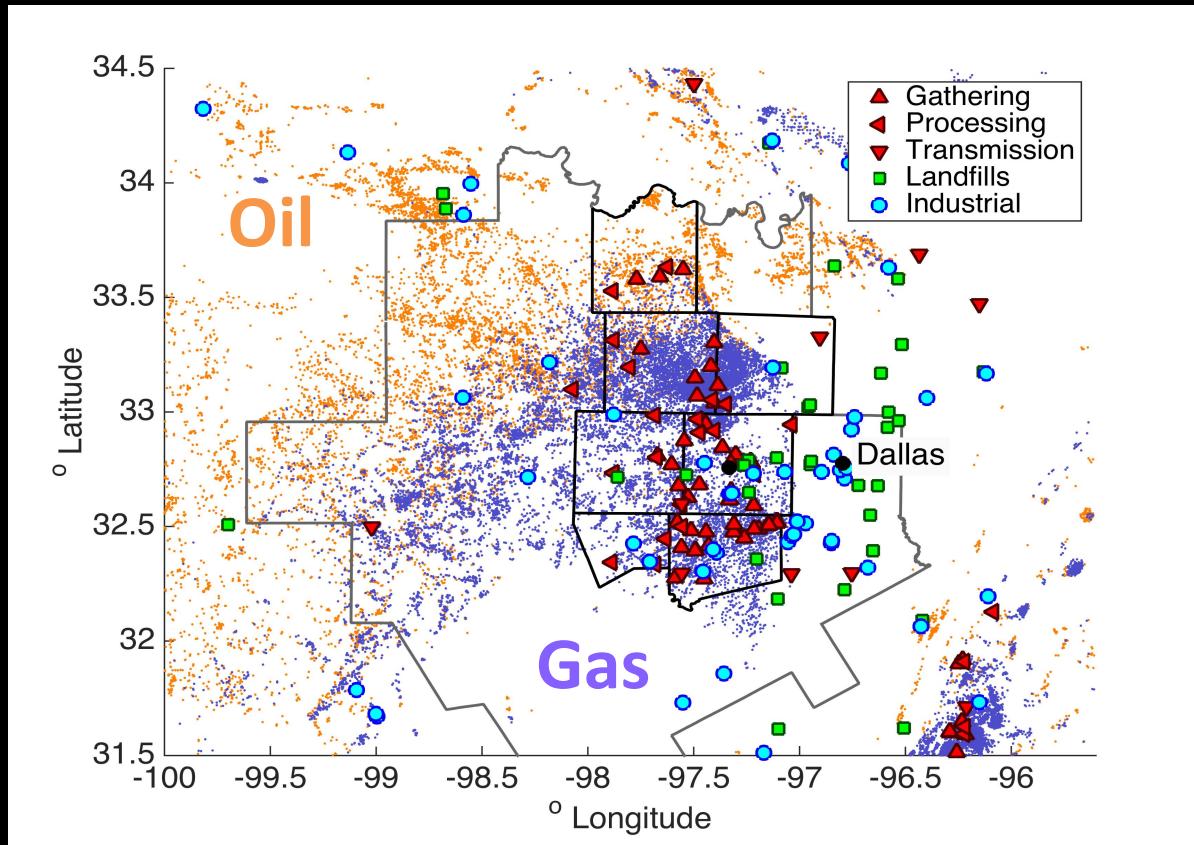

Mass Balance example

- Does not require complicated transport models
- Features are consistent throughout the mixed layer

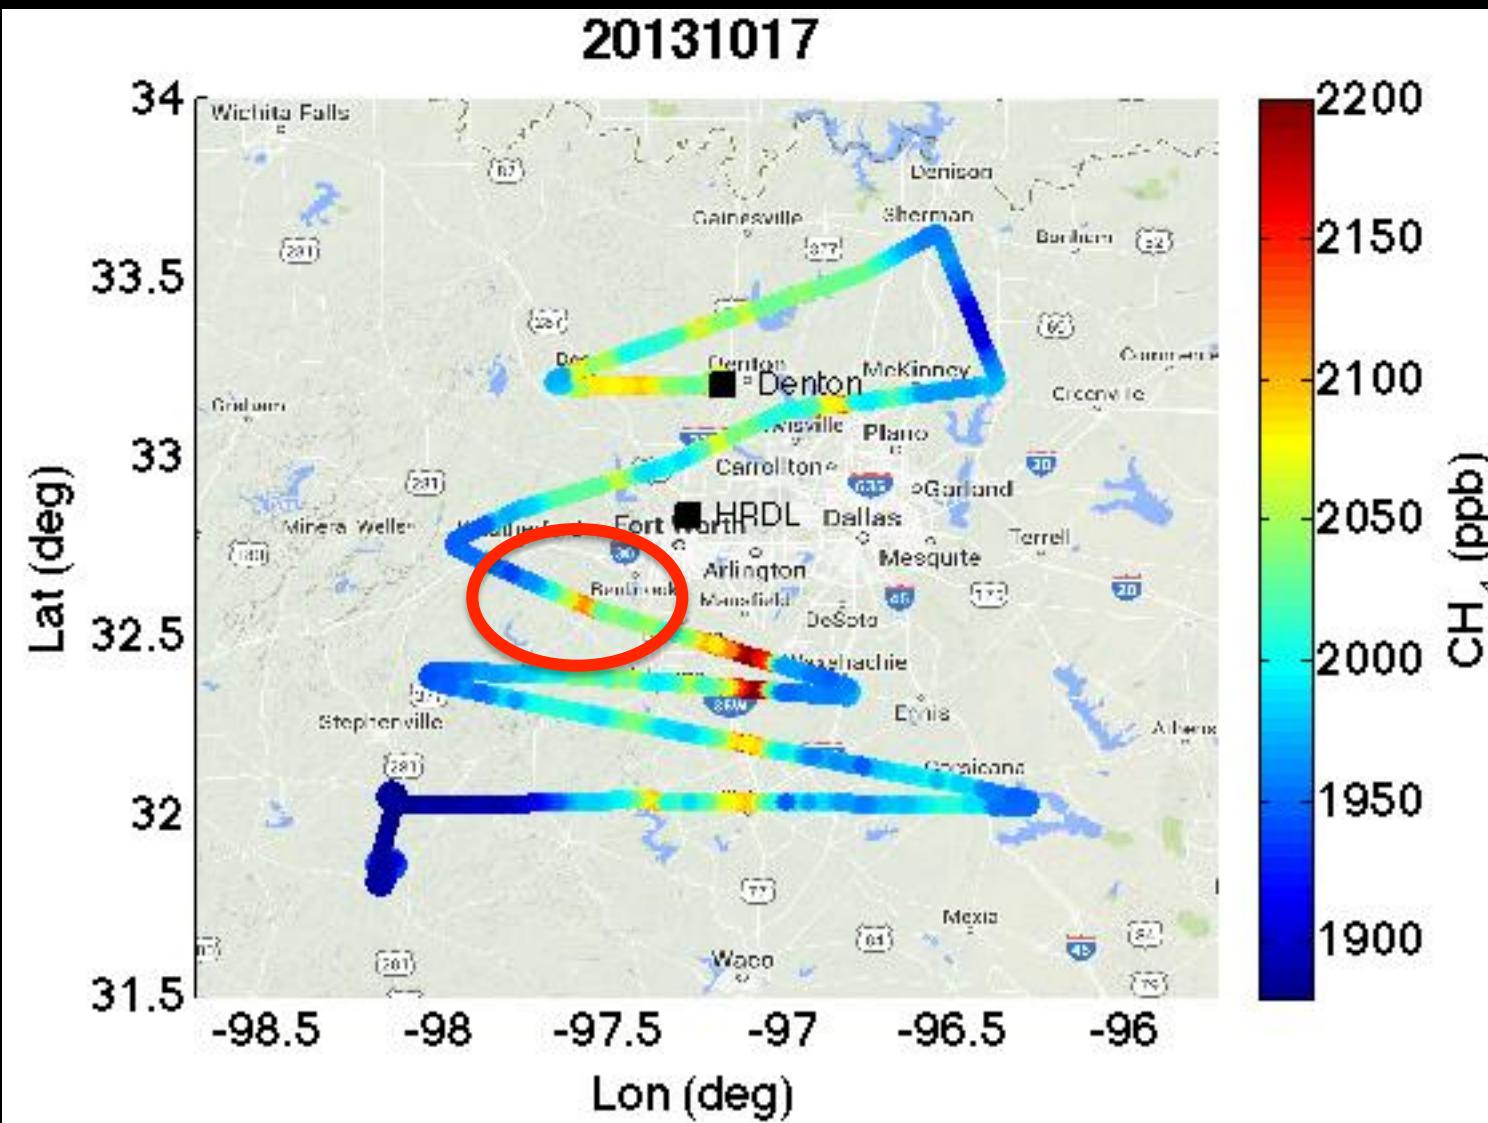

Scaling down

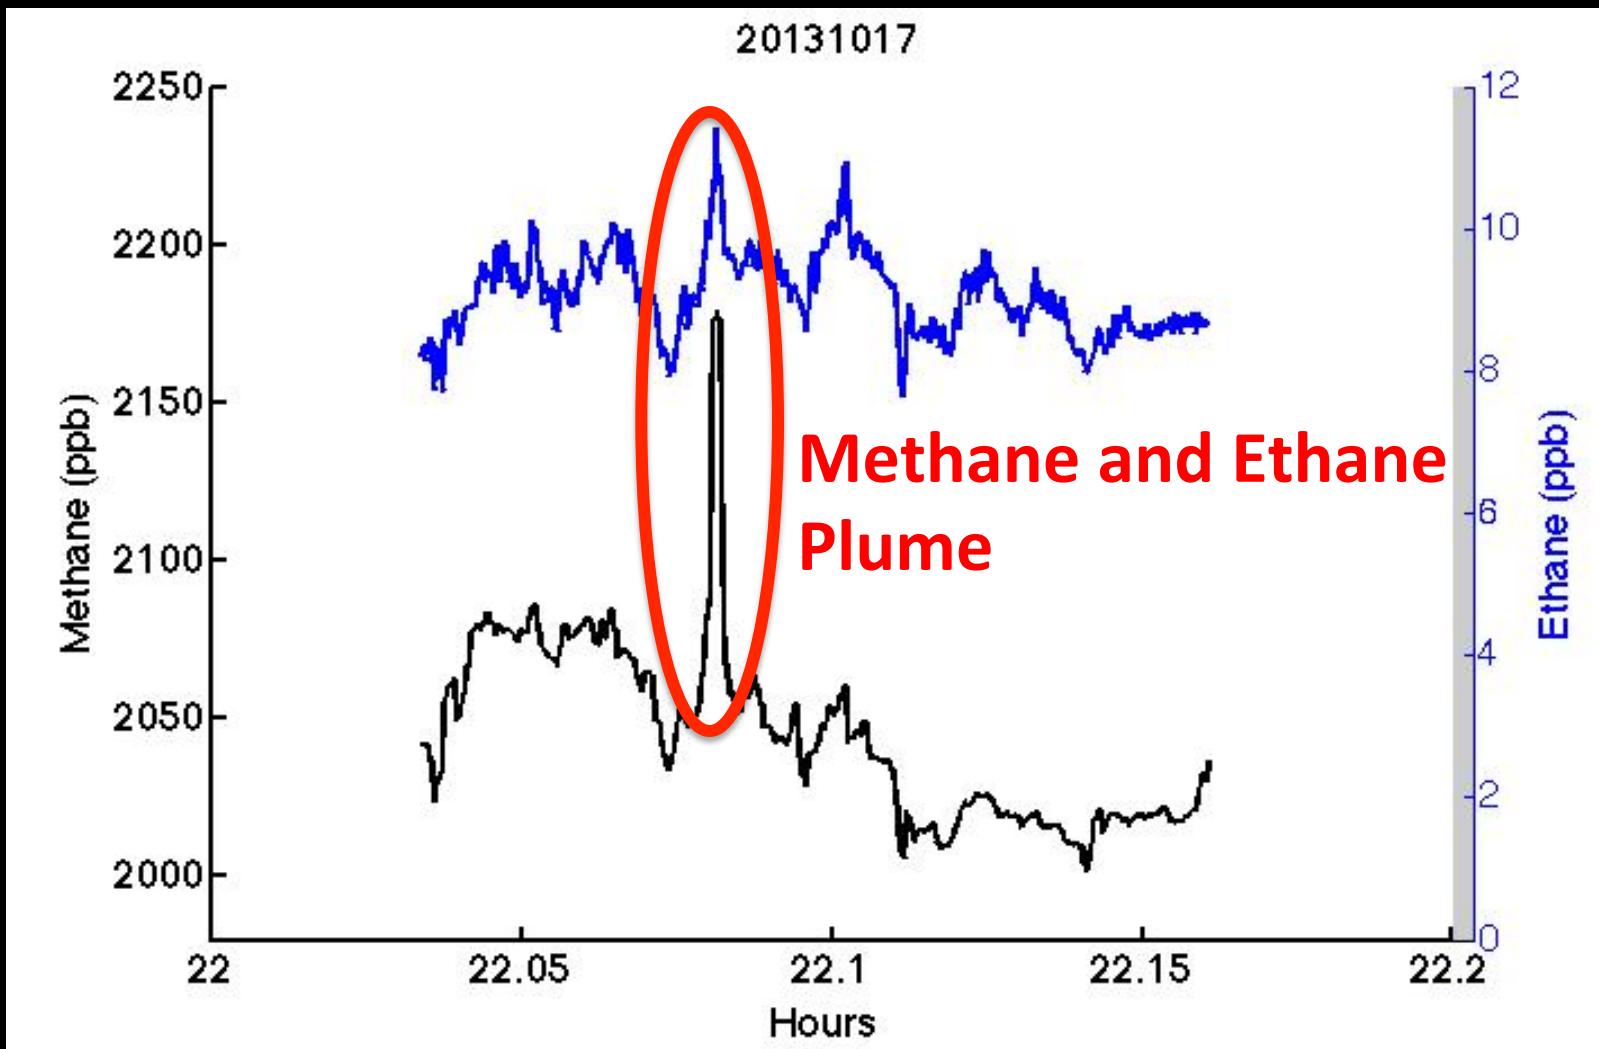

The Barnett Shale region has more than oil and gas wells. There were also land fills and some agricultural sources that need to be accounted for. Two approaches:

- 1) Point source identification to quantify role of large emitters
- 2) Use of tracers to attribute source of regional emissions

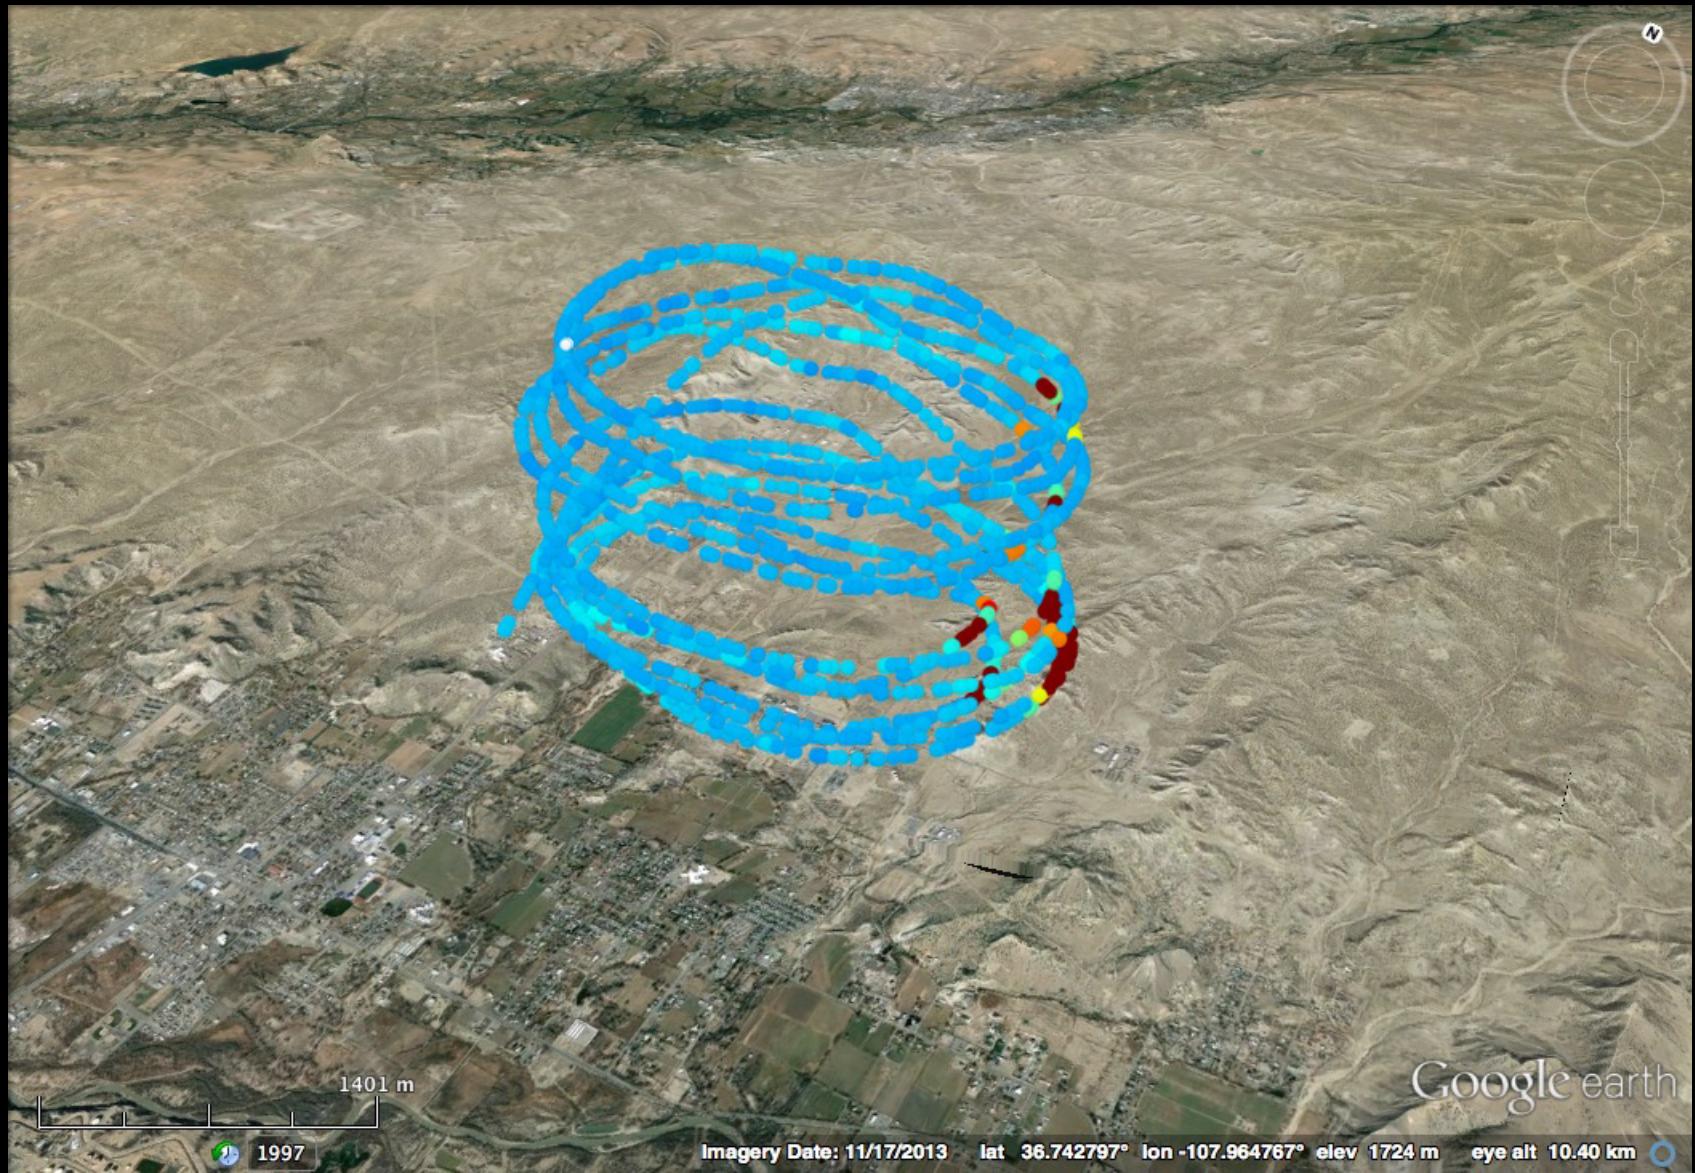

Point Source Identification

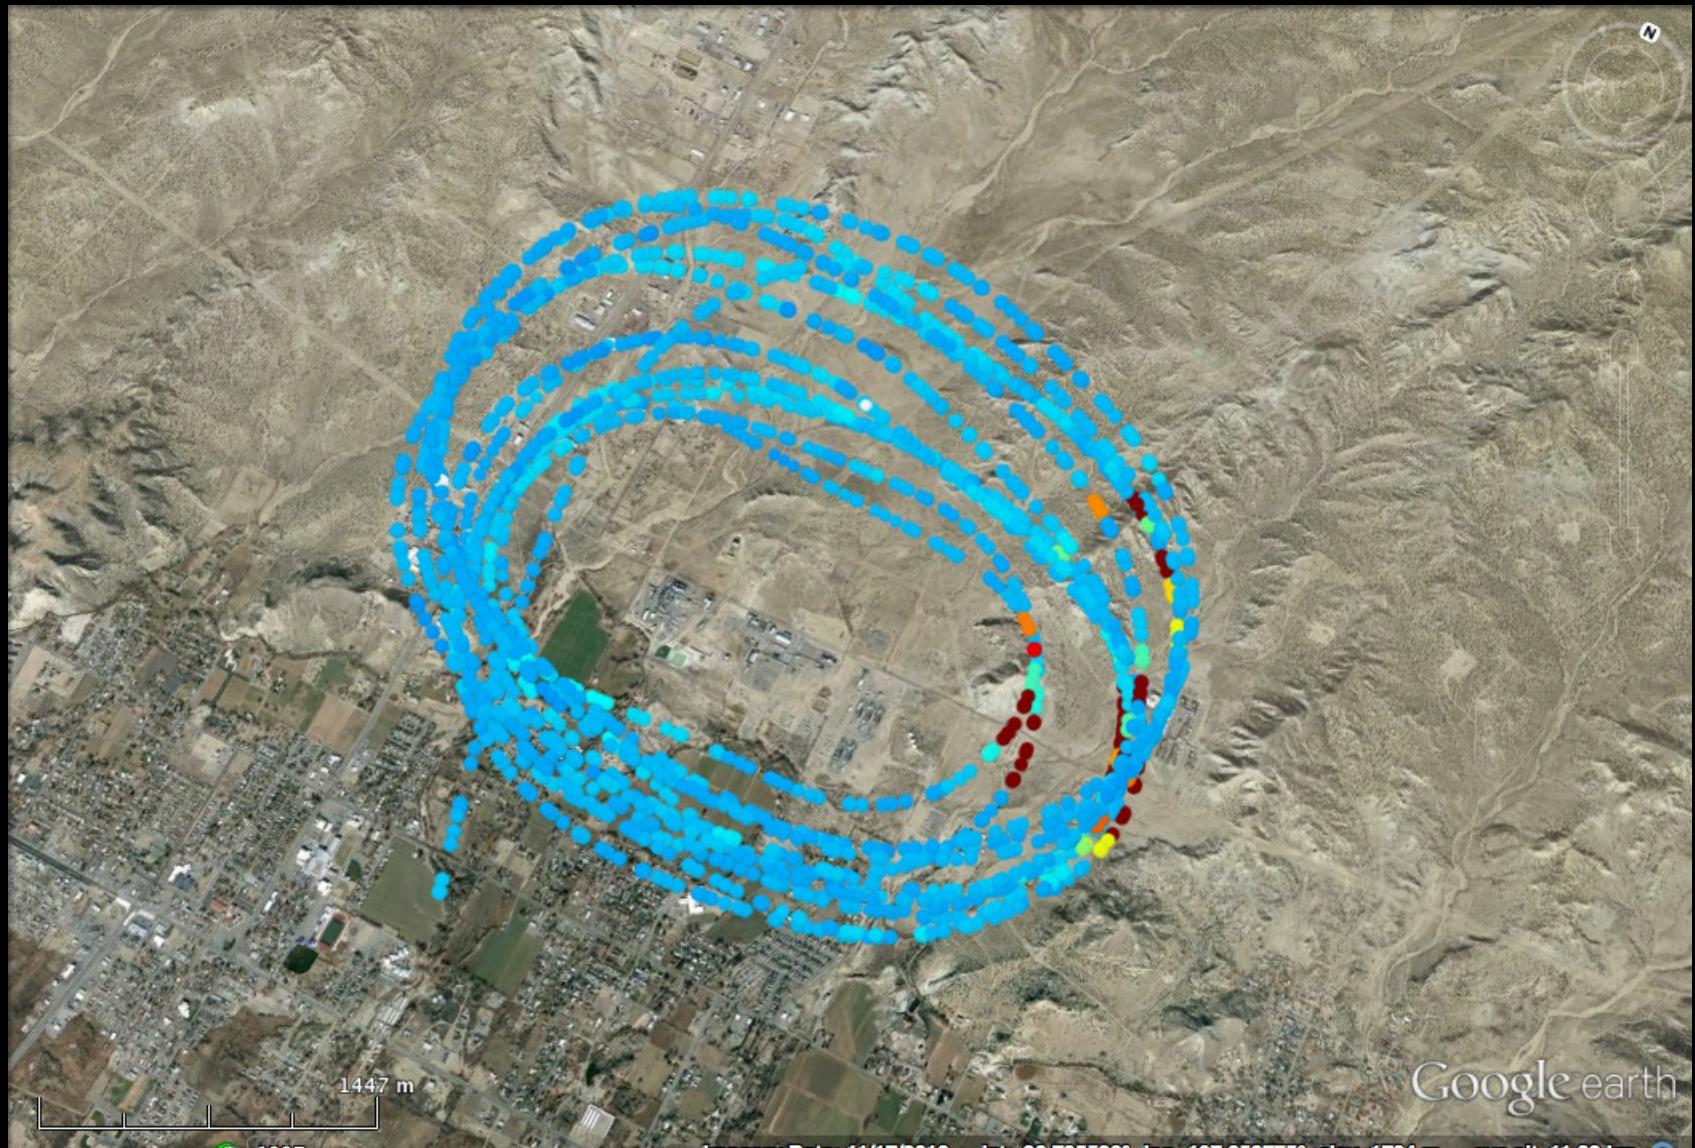

Point Source Identification

Point Source ID and Quantification

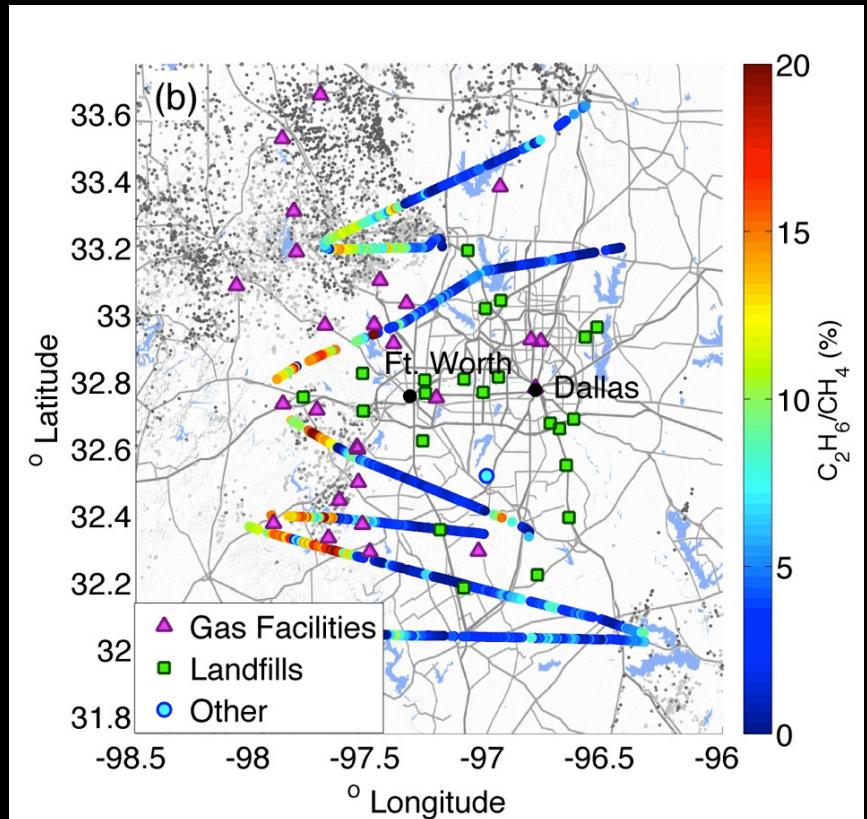

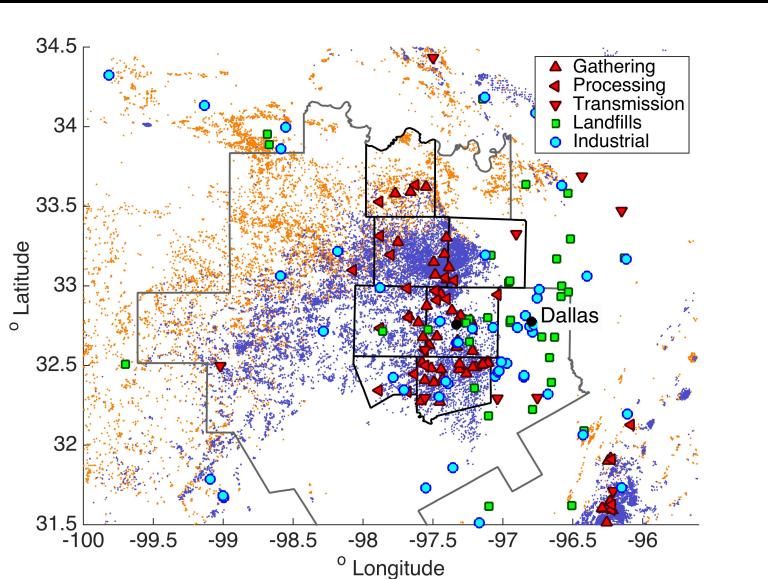

Point Source ID and Quantification

Point Source ID and Quantification

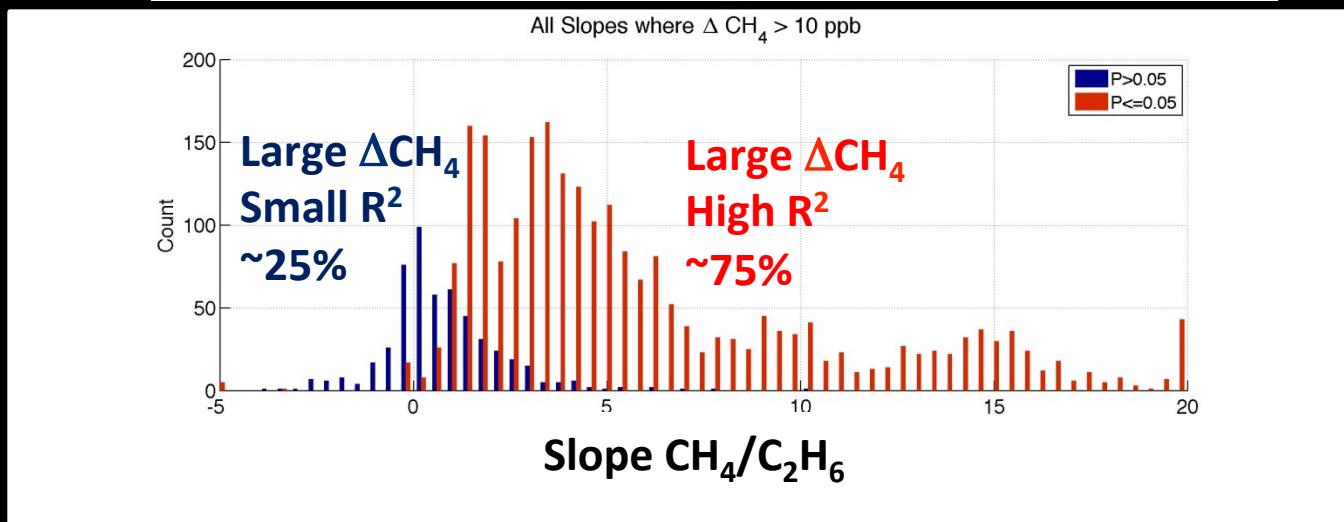

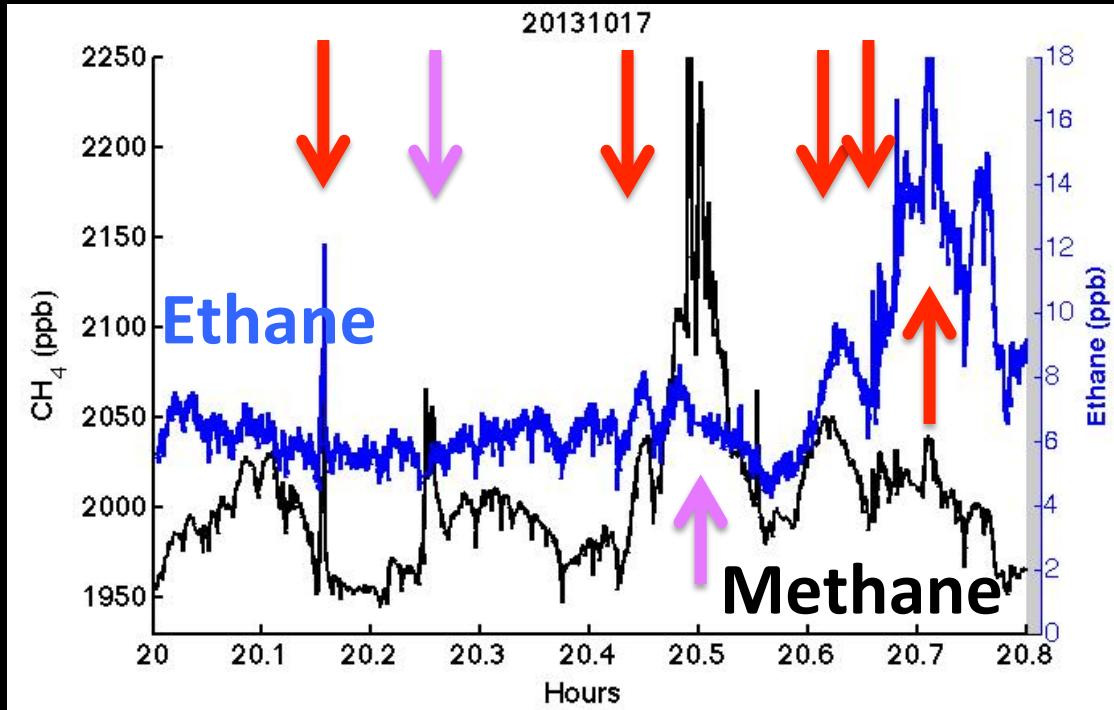

Attribution of emission

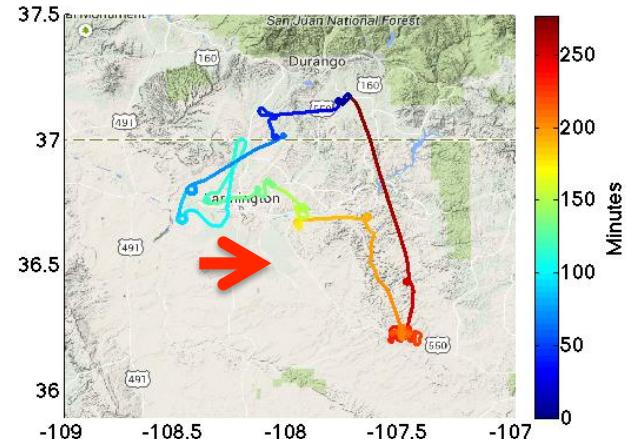

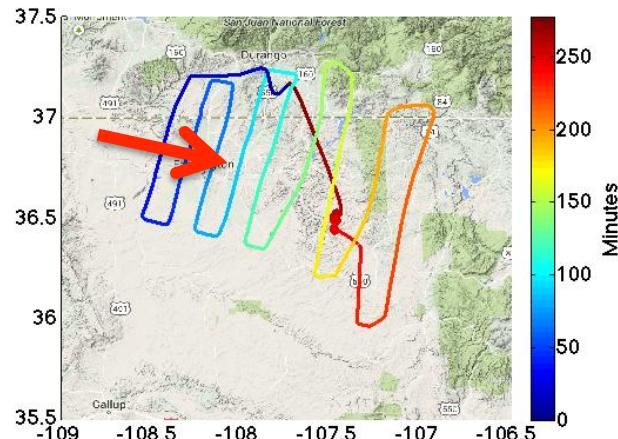

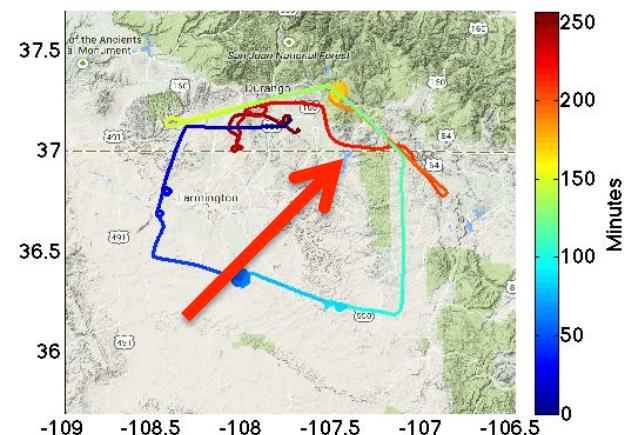

In the Barnett Shale region we used ethane and ^{13}C of CH_4 to separate oil and gas emitters from landfills and agricultural emissions.

Attribution of emission

Transect of ethane and methane in Barnett shows both fossil fuel and non fossil emitters
